Summary

Its parts continuously work in unison to fulfill a singular task, transforming the raw materials of your food into the nutrients and energy that keep you alive. First, there's the gastrointestinal tract, a twisting channel that transports your food and has an internal surface area of between 30 and 40 square meters. Third, the body's enzymes, hormones, nerves, and blood all work together to break down food, modulate the digestive process, and deliver its final products. Finally, there's the mezzantery, a large stretch of tissue that supports and positions all your digestive organs in the abdomen, enabling them to do their jobs. Then your food finds itself at the rim of a 25 cm long tube called the esophagus, down which it must plunge to reach the stomach. Hormones, secreted by cells in the lining, trigger the release of acids and enzyme-rich juices from the stomach wall that start to dissolve the food and break down its proteins. These hormones also alert the pancreas, liver, and gallbladder to produce digestive juices and transfer bile, a yellowish green liquid that digests fat, in preparation for the next stage. After 3 hours inside the stomach, the once shapely bolus is now a frothy liquid called chime, and it's ready to move into the small intestine. Here, it dissolves the fats floating in the slurry of chime so they can be easily digested by the pancreatic and intestinal juices that have leached onto the scene. The colon squeezes this byproduct into a pouch called the rectum, where nerves sense it expanding, and tell the body when it's time to expel the waste.

Key Points

- Hormones, secreted by cells in the lining, trigger the release of acids and enzyme-rich juices from the stomach wall that start to dissolve the food and break down its proteins.
- These hormones also alert the pancreas, liver, and gallbladder to produce digestive juices and transfer bile, a yellowish green liquid that digests fat, in preparation for the next stage.
- Here, it dissolves the fats floating in the slurry of chime so they can be easily digested by the pancreatic and intestinal juices that have leached onto the scene.
- Its parts continuously work in unison to fulfill a singular task, transforming the raw materials of your food into the nutrients and energy that keep you alive.
- Finally, there's the mezzantery, a large stretch of tissue that supports and positions all your digestive organs in the abdomen, enabling them to do their jobs.
- Then your food finds itself at the rim of a 25 cm long tube called the esophagus, down which it must plunge to reach the stomach.
- First, there's the gastrointestinal tract, a twisting channel that transports your food and has an internal surface area of between 30 and 40 square meters.
- Third, the body's enzymes, hormones, nerves, and blood all work together to break down food, modulate the digestive process, and deliver its final products.

True or False

Q: True or False: And every last scrap makes its way through the digestive system.

A: True

Q: True or False: We produce about 1.5 liters of this liquid each day.

A: True

Q: True or False: That's over 365 kilograms a year per person, and more than 28,800 kilograms over the course of a lifetime.

A: True
